→ Scale of Virtual Reality

It shows how the real world gradually transitions into a completely virtual environment. Between these two extremes lies mixed Reality (MR), where both real and virtual elements are combined. Within this range, Augmented Reality (AR) adds digital information to the real world without strong interaction, while Augmented Virtuality (AV) mainly presents a virtual environment that stills ~~rep~~ respond to the physical world.

Augmented reality adds digital objects to the real world but these objects do not strongly interact with it. In the middle lies Mixed reality, where real and virtual elements interact with each other in real time, making the experience more immersive.

~~The~~ The 360-degree video is created using a special camera like Insta 360X3 that captures all directions at once. Such videos are widely used in education, training and virtual experiences because they give a realistic sense of presence, almost as if the viewer is physically present in that environment.

Immersive Virtual Reality is a technology that creates a fully virtual environment where users feel present inside it using devices like VR headsets and sensors, making experiences more interactive and realistic.

Features of VR

Real time Response - System responds instantly to user movements.

Sensory Feedback - It includes visual, sound, and sometimes touch

Interaction - Ability to interact with virtual objects in real time.

Virtual Reality (VR) is a powerful and evolving technology that creates immersive and interactive digital environment It enhances user experience by providing realistic simulations and is widely used in fields like education, gaming, healthcare and training. overall, VR has great potential to transform the way people learn work, and experience the world. However, challanges like high cost, technical limitations and potential health effects still need to be addressed, making experiences more engaging, effective and lifelike.
